Technical Description and Documentation of Project

Description of Project

Purpose

The purpose of the compiler design project is to create a simulacrum of a low-level compiler, abstracting the need of memory, token, and pointer handling, to teach us diverse things about the nature of creating, understanding, and working of a language. In this project, you must construct your compiler from the formal grammar to the lexical analyzer, to the parser, till the virtual machine that will compile your language.

Test Cases and Project Requirements

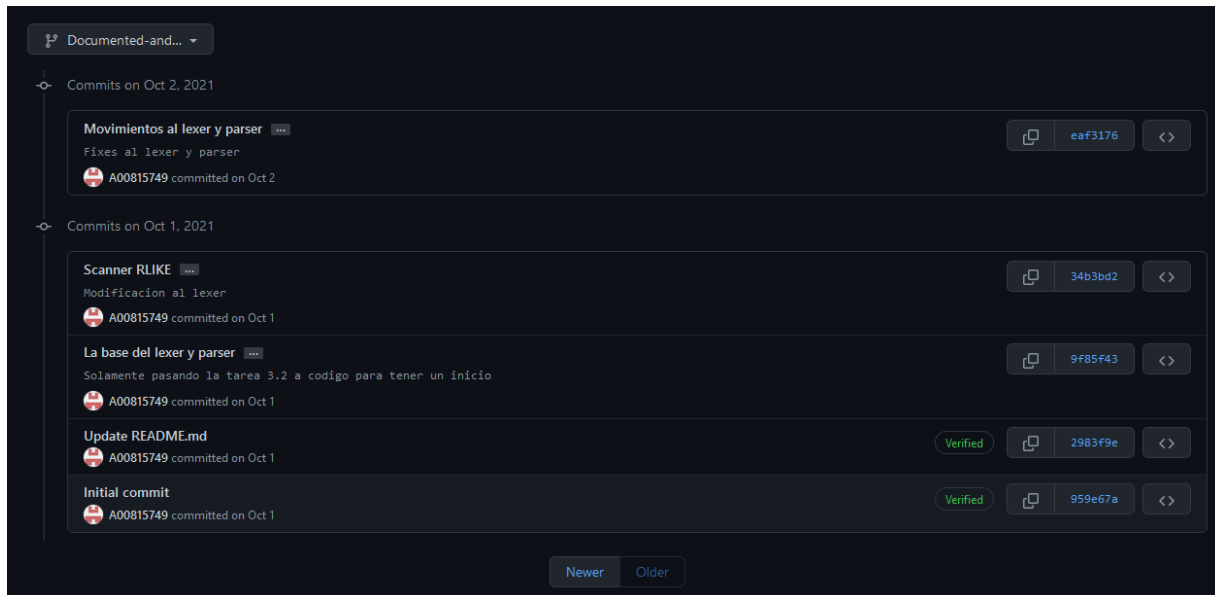

We were provided with a document that described the specific requirements in the language, also guiding with a generic format of a program writing on that specific language. The language follows a standard structure for programming languages, giving us a specific list that we must complete for general approval:

- Variable declarations in a local and global context
- Function declarations
- Void Functions and return functions
- Handling of Int, Float and char variables
- Vector handling of the previous variables
- Expression Handling
- Diverse statutes:
 - Assign, in which an identifier (from now on written as id) is assigned with a given value, in both simple variables, vectors and function calls
 - Read, in which the user can read from input, and store data in the defined id.
 - Write, in which a user can print on terminal the value of the id
 - Decision statutes, in which a user can follow the standard structure of an if-else decision, by reading expressions.
 - Looping statutes, which include:
 - Conditional: While structure
 - No Conditional: for structure
- Arithmetic, Logical and Relational operations for the appropriate ids
- And special functions that accept a list of numbers

Description of General Development Process of the Project

The development process was started in last days of September, in which the bases of the formal grammar for the language, giving form to a half-finished base to start building

up upon, which was the first deliverable, at the same time that a source control site was used to leave a documentation trail.

eaf3176f5fe48b0129cb455b33b0ccfdade497679, sample commits from the Github

Unfortunately, this gave rise to a sense of arrogance, letting slip the project schedule, in which almost all the month of October was lost, with the only advances in the project dealing with theoretical musings and grammar drawings.

It wasn't till the month of November that urgency took hold, and full-time work was made to the project, with one full day being dedicated to it.

It wasn't till the seventeenth of November that, being sincere, panic began to settle in, which caused a surge of effort to be put into the compiler, with predictable consequences.

Several hours each day was devoted to working on the project, as seen above, but due to the hurried nature of the development, the code quality began to descend dramatically, till a revelation was discovered on the morning of the twenty-two of November.

2e9cf24723b967ab5d9521d75ed43eb90b2f4666

The compiler was a literal hodgepodge of what our field calls 'spaghetti' code. Untested sections, unnecessary data structures, bizarre logic, and all the sins against coding were committed, and the need for a massive reformatting following a streamlined logic was needed, helped by some useful examples and tutorials on the Internet for token handling, stack data structures, Python characteristics, etcetera.

Entire days have been used up in the fires of this project, and the only breaks allowed were for sleeping, which was fitful, but in the end we are here. Testing, commenting code, taking notes and all was done, and the entire project effort, (which was slated for approximately 9 weeks of 5 hours each week, in the best-case scenario, not accounting for time lost studying for tests and class exercises) with approximated needed work hours of about ~35 hours, over 30 hours and counting of work has been done in the past 3 days.

And so, we reach the end.

As of now, this student is hard at work documenting, and leaves the following link for the entire project commit history:

<https://github.com/A00815749/Compiladores2021/commits/main>

Student Thoughts and Reflections

I consider this project to be the hardest thing I had done on my long academic life, while at the same time I also think it was somewhat fun to work on this jumbo project, if I ignore the stress and anxiety in general. I joke, mostly, but something I consider that is a drawback of this kind of project, is the sheer amount of time wastage following dead ends, consequence of the open nature of the work, getting many of my fellow students, and past semester me, as casualties in the road to graduating this engineering course. Maybe an alternative would be subdividing the work as smaller open projects? Even another way would be doing isolated but gradable exercises, like developing a grammar for certain requirements, or developing the neuralgic points for a language, or editing the virtual machine so that it can process the list of Quadruples of this parser. All this can lead to learning the concepts that will be stuck in my head for years, like data structure handling, grammar creating, debugging big software projects, etcetera.

As a final thought, I just want to make clear that this class is one of the best classes I had taken, even if it implies a lot of work, and I express my thanks to our two teachers.

Language Description

Name of Language

The Base Language that this project was based upon was the R language, which is a statistical computing language, which is fitting, I suppose for the various special methods we were requested. If I had to seriously name my final code language, I would use the end file notation of my parser output via the quadruple list, which is .mir, which originally meant 'my r' but I think the reference to the space stations its nice, so it shall be the Mir language.

Main characteristics of the Mir language

This language has the basic functionality of a simple high level programming language, with a need for strong typing, due to an easier implementation. With the exception of the functions and conditionals, every line must end in a semicolon, every variable must be explicitly declared with its kind, certain sections of code must remain constant when being worked upon, there are certain limits of memory that must be taken in account, only vectors of one dimension are supported, and the nifty addition of some simple statistical methods.

Error lists, in Compilation and Execution

- "FUNCION EXISTENTE REPETIDA"
- "ID DE VARIABLE Y/O PROGRAMA REPETIDA"
- "OPERACION INVALIDA, MISMATCH DE TIPOS"
- "VARIABLE DECLARADA MULTIPLES VECES"
- "MISMATCH DE TIPOS"
- "TIPO DE DATO NO ACEPTADO"
- "VARIABLE SIN TIPO"
- "VARIABLE SIN VALOR"
- "NO EXISTE LA VARIABLE QUE SE BUSCA"
- "OPERACION INVALIDA"
- "FUNCION ESPERABA NO PARAMETROS"
- "FUNCION CON NUMERO DE PARAMETROS ERRONEO"
- "VARIABLE VECTOR SIN DIMENSIONES"
- ~~~~~DIVIDER BETWEEN COMPILING AND EXECUTION~~~~~
- "NONE IN HERE" + Quadruple operation being handled
- "TYPE MISMATCH" + Quadruple operation being handled
- "NOT A CHAR" + Quadruple operation being handled
- "NO EXISTENCE FOR THIS VALUE" + variable virtual address
- "TRYING NONES IN THE SUM QUADS", and REST, TIMES, DIVIDE >, >=, <=, ==,<>,AND,OR
- "VECTOR INDEX OUT OF BOUNDS"

Compiler Description

Physical Computer Equipment, Language and Special Required Utilities

This project was mainly worked on a custom build work desktop, using the Python language as the lexical analyzer, parser, and virtual machine via the judicious use of PLY, using the next special libraries, courtesy from their creators:

- Time library
- Sys library
- Os library
- Lex and yacc form PLY library
- Statistics library
- Matplotlib.pyplot library

Lexical Analyzer Description

The final list of tokens in the language is as follows, starting with the reserved words:

```
reserved = {
    'Program' : 'PROGRAM', # program reserved word
    'principal' : 'PRINCIPAL', # main reserved word
    'function' : 'FUNCTION', # function reserved word
    'VARS' : 'VARS', # VARS reserved word
    'int' : 'INT', # int reserved word
    'float' : 'FLOAT', # float reserved word
    'char' : 'CHAR', # char reserved word
    'str' : 'STR', # STR reserved word
    'return' : 'RETURN', # return reserved word
    'read' : 'READ', # read reserved word
    'write' : 'WRITE', # write reserved word
    'and' : 'AND', # and reserved word
    'or' : 'OR', # or reserved word
    'if' : 'IF', # if reserved word
    'then' : 'THEN', # then reserved word
    'else' : 'ELSE', # else reserved word
    'while' : 'WHILE', # while reserved word
    'do' : 'DO', # do reserved word
    'for' : 'FOR', # for reserved word
    'to' : 'TO', # to reserved word
    'void' : 'VOID', # void reserved word
    'true' : 'TRUE', # TRUE reserved word
    'false' : 'FALSE', # FALSE reserved word
    'media' : 'MEDIA', # special function average
    'mediana' : 'MEDIANA', # special function median
    'moda' : 'MODA', # special function mode
    'varianza' : 'VARIANZA', # special function variance
    'stdev' : 'STDEV', # special function simple regression
    'plotxy' : 'PLOTXY', # special function plot two data columns
```

Following that, we have the rest of the tokens:

```
# list of TOKENS
tokens = [
    'STRING', # String token
    'ID', # ID token
    'PLUS', # + symbol
    'REST', # - symbol
    'TIMES', # * symbol
    'DIVIDE', # / symbol
    'GREATER', # > symbol
    'GREATERAND', # >= symbol
    'LESSER', # < symbol
    'LESSERAND', # <= symbol
    'SAME', # == symbol
    'NOTSAME', # <> symbol
    'NOT', # ! symbol
    'EQUAL', # = symbol
    'LEFTBR', # { symbol
    'RIGHTBR', # } symbol
    'LEFTPAR', # ( symbol
    'RIGHTPAR', # ) symbol
    'LEFTSQR', # [ symbol
    'RIGHTSQR', # ] symbol
    'COLON', # : symbol
    'SEMICOLON', # ; symbol
    'COMMA', # , symbol
    'CTEINT', # constant int
    'CTEFLOAT', # constant float
    'CTECHAR', # constant char
```

Finally, we have the following construction patterns via Regex handling of the tokens:

- SEMICOLON = r'\;'
- COLON = r'\:'
- COMMA = r'\,'
- EQUAL = r'\='
- SAME = r'\=\='
- LEFTPAR = r'\('
- RIGHTPAR = r'\)'
- LEFTBR = r'\{'
- RIGHTBR = r'\}'
- LEFTSQR = r'\['
- RIGHTSQR = r'\]'
- STRING = r'\".*\"'

- PLUS = r'\+'
- REST = r'\-'
- TIMES = r'*'
- DIVIDE = r'\/'
- GREATER = r'\>'
- GREATERAND = r'\>|='
- LESSER = r'\<'
- LESSERAND = r'\<|='
- NOTSAME = r'\<|>'
- NOT = r'\!'
- CTECHAR = r'"'\.\\'
- CTEFLOAT = r'\-?d+\. \d+'
- CTEINT = r'\-?\d+'
- ID r'[a-zA-Z_][a-zA-Z0-9]*'

Special thanks to <https://regex101.com/> for providing fast and detailed checkups of the regular expressions.

Intermediate Code Generation and Semantical Analysis

One of the core structures of the compiler it's the Quadruple class, which is an object that has the following construction:

```
class Quadruple :
    def __init__(self, operator, LeftOperand, RightOperand, result):
        global QUADRUPLESlist
        self.QUADcounter = len(QUADRUPLESlist) + 1 # The number of
        self.operator = operator
        self.LeftOperand = LeftOperand
        self.RightOperand = RightOperand
        self.result = result
```

In which we have 5 attributes, with the typical 4 of a quadruple container, and the extra quadcounter for jump purposes, and future VM use. It must be noted that the attribute operator follows a special hash map, in which depending on what token it has, it stores a numerical value, as follows:

```

HASHOFOPERATORSINquads = {
    '+' : 1,
    '-' : 2,
    '*' : 3,
    '/' : 4,
    '>' : 5,
    '>=' : 6,
    '<' : 7,
    '<=' : 8,
    '==' : 9,
    '<>' : 10,
    '=' : 11,
    'READ' : 12,
    'WRITE' : 13,
    'and' : 14,
    'OR' : 15,
    'GOTO' : 16,
    'GOTOF' : 17,
    'GOTOV' : 18,
    'ERA' : 19,
    'VER' : 20,
    'ENDPROC' : 21,
    'PARAM' : 22,
    'GOSUB' : 23,
    'MEDIA' : 24,
    'MEDIANA' : 25,
    'MODA' : 26,
    'STDEV' : 27,
    'VARIANZA' : 28,
    'PLOTXY' : 29,
    'RETURN' : 30,
    '' : -1
}

```

The semantical considerations seen on this project was primarily the responsibility of an external class, aptly named the Semantic Cube, which has an internal method to do semantic checks, accepting two operands and an operator, and returning the appropriate type for the semantic sensor. Its structure is presented on the following image:

```

class Semanticcube:
    def __init__(self):
        # Dict for Our Symbols for the Rlike lang
        self.operatorsymbol = {
            1: '+',
            2: '-',
            3: '*',
            4: '/',
            5: '<',
            6: '<=',
            7: '>',
            8: '>=',
            9: '==',
            10: '<>',
            11: '&',
            12: '|',
            13: '=',
            14: 'and'
        }

        # dict types for the lang
        self.types = {
            1: 'int',
            2: 'float',
            3: 'char',
            4: 'bool',
            5: 'CTEINT',
            6: 'CTEFLOAT',
            7: 'CTECHAR',
            8: 'CTESTRING',
            9: 'ERROR',
        }

        self.commonsensor = {
            #By order, starting with types
            #Integer left hand
            self.types[1]: {
                #int right hand
                self.types[1]: {
                    self.operatorsymbol[1] : self.types[1], #integer adding integer results in integer, and so on and on
                    self.operatorsymbol[2] : self.types[1],
                    self.operatorsymbol[3] : self.types[1],
                    self.operatorsymbol[4] : self.types[1],
                    self.operatorsymbol[5] : self.types[4],
                    self.operatorsymbol[6] : self.types[4],
                    self.operatorsymbol[7] : self.types[4],
                    self.operatorsymbol[8] : self.types[4],
                    self.operatorsymbol[9] : self.types[4],
                    self.operatorsymbol[10] : self.types[4],
                }
            }
        }

```

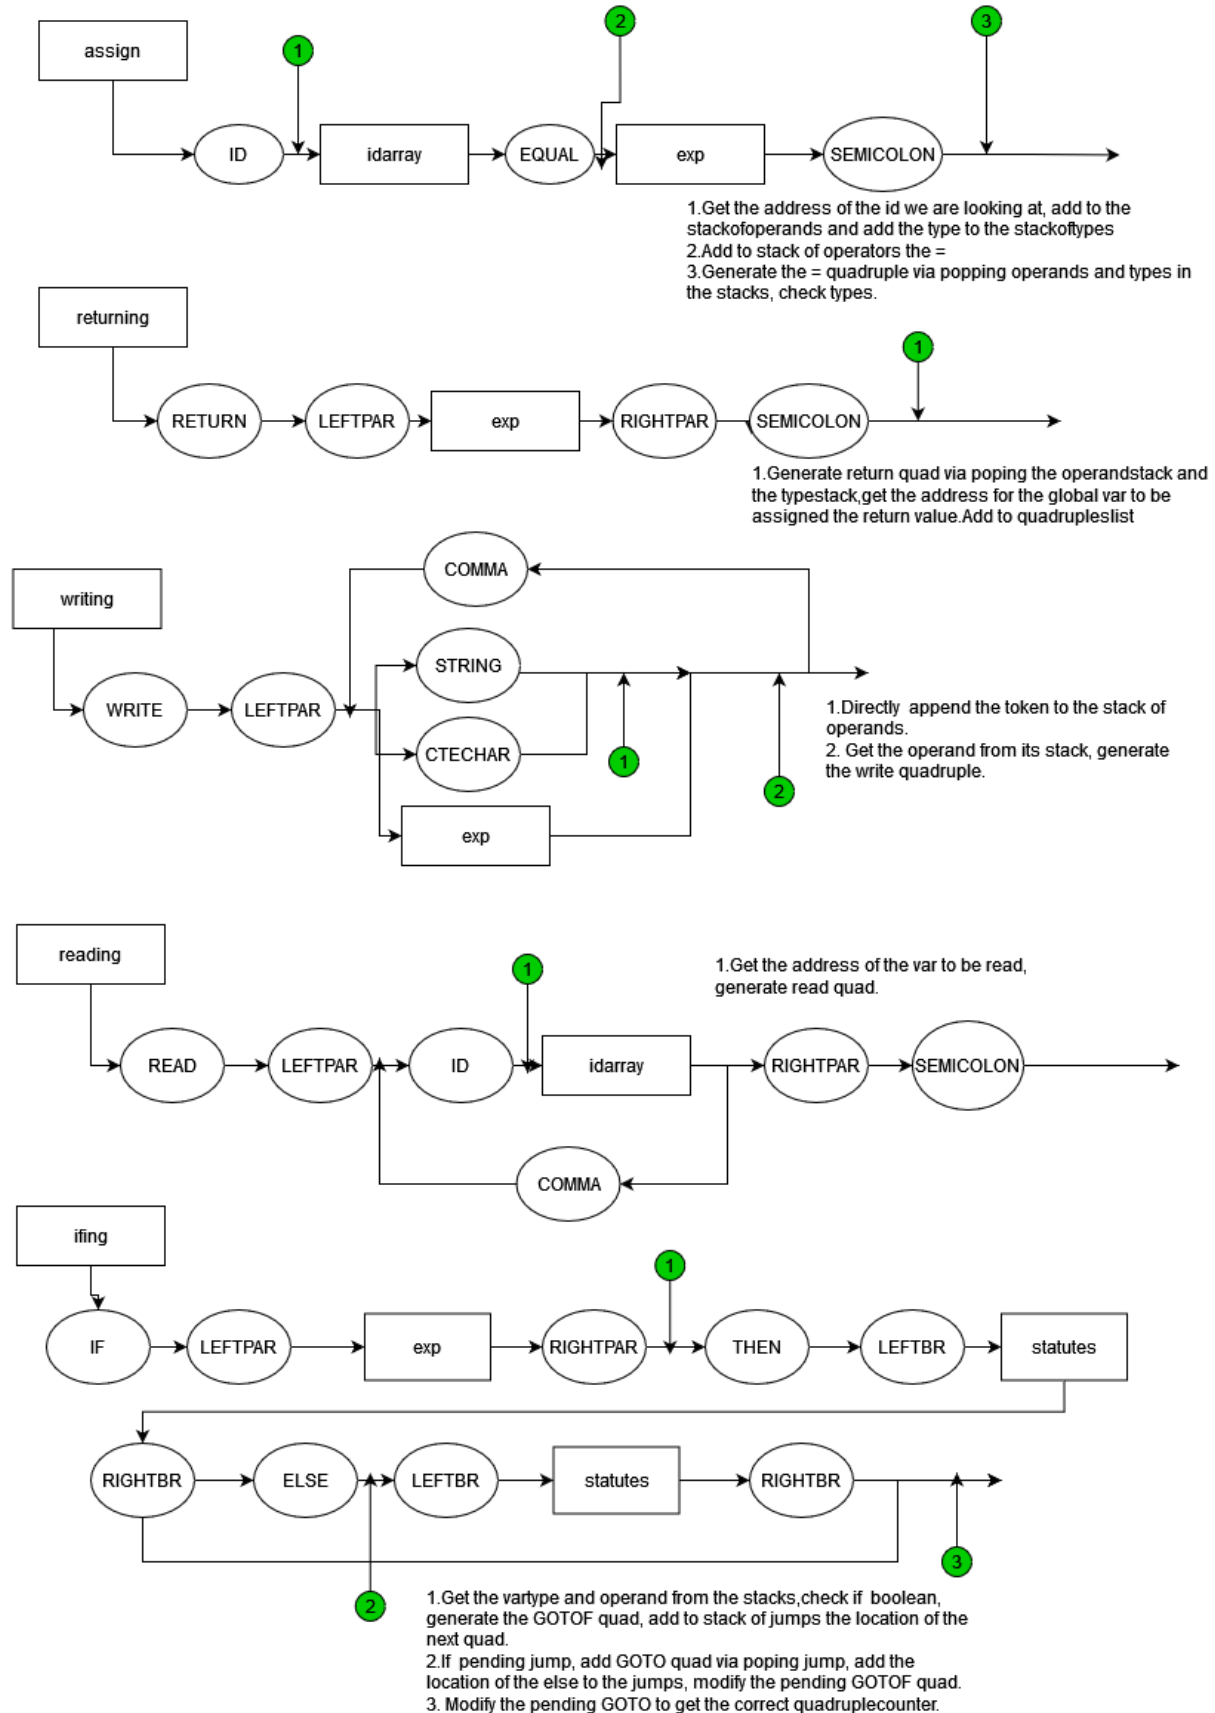

We can see that the class semantic cube has three attributes, a set of operator symbols, which stores the symbols that our language will use for operations. Then we have a second set of types which will be assigned a certain numerical key for ease of use. And finally, we have a nested set of sets, in which we have three layers, the first layers represent the left type of an operation, the second level represents the right hand of an operations, and the third layer in which we store the specific operator we are working with. Finally, the combined 3 dimensions point to a single value, which is the result of the combining of the previous two types, leading to a useful common sensor, giving you which types can work with which operators, and gives you an error message when you break the logic of the code.

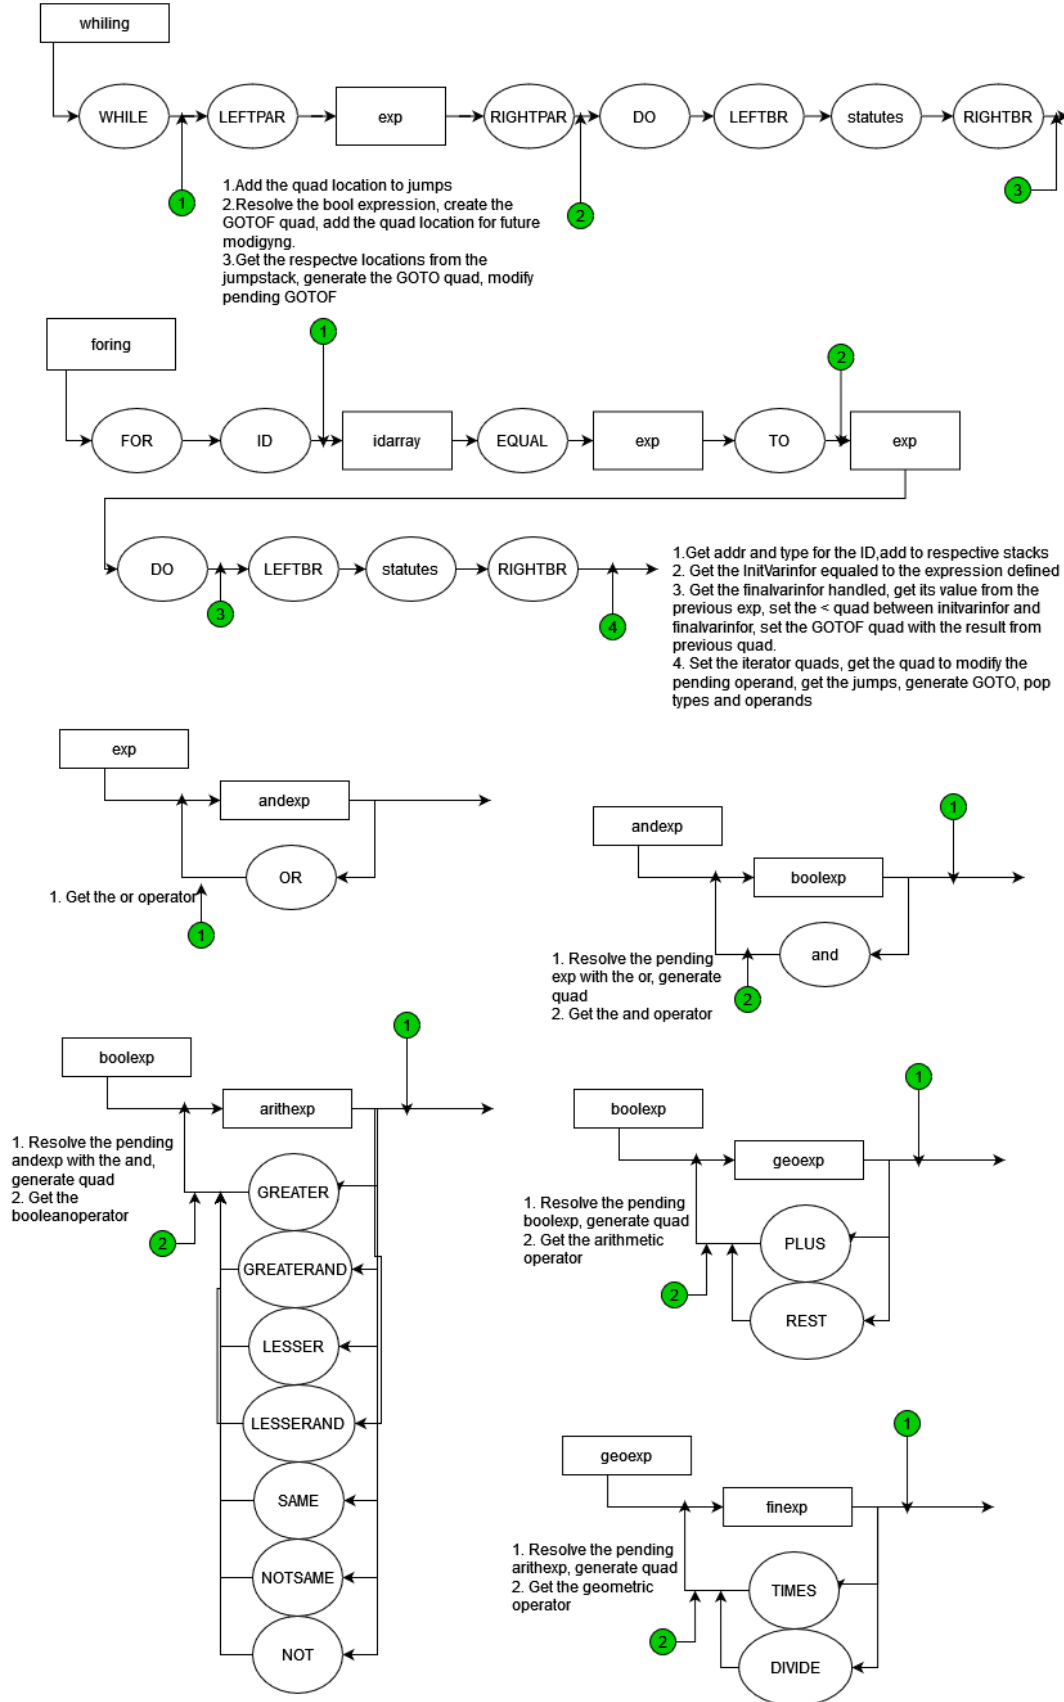

Next, we have the exciting part of the syntaxis diagram with the noted neuralgic points, giving us the code actions that we need to set up the inner works of our compiler:

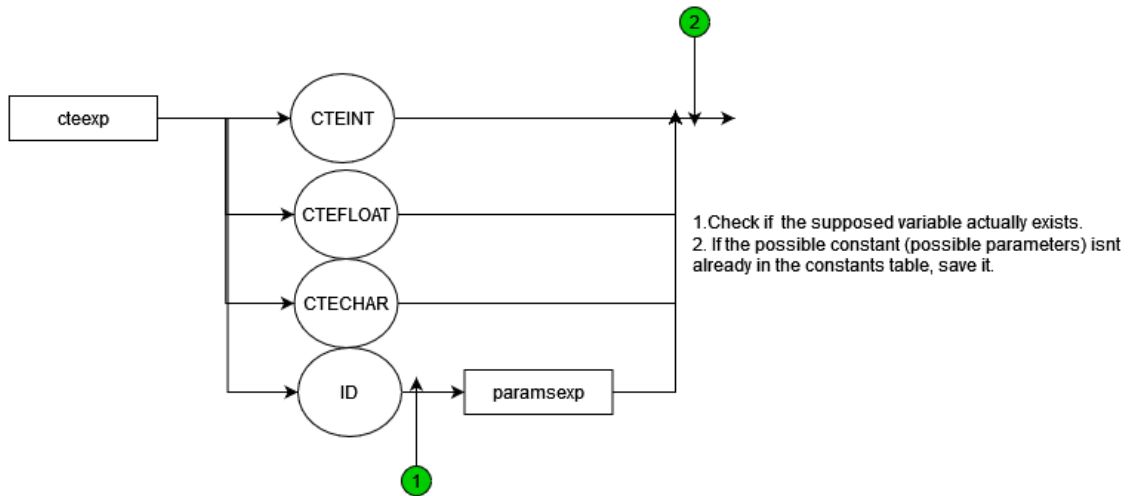

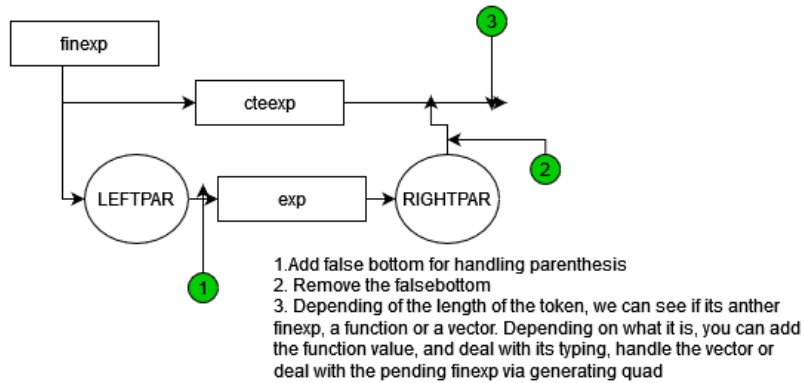

Full resolution inside the project folder.

Memory administration during the compilation process

During the compilation process, we had to abstract away the storing of values, via the use of ‘virtual’ addresses, which stand in place of possible memory blocks. Due to this, we must organize a virtual memory map for the storing of our values. Its structure it's the following:

```
GLOBALINTcounter = 1000 - 1 # BLOCK of 2000 spaces
GLOBALFLOATcounter = 3000 - 1
GLOBALCHARcounter = 5000 - 1
LOCALINTcounter = 7000 - 1
LOCALFLOATcounter = 9000 - 1
LOCALCHARcounter = 11000 - 1
TEMPINTcounter = 13000 - 1
TEMPFLOATcounter = 15000 - 1
TEMPCHARcounter = 17000 - 1
TEMPBOOLcounter = 19000 - 1
CONSTINTcounter = 21000 - 1
CONSTFLOATcounter = 23000 - 1
CONSTCHARcounter = 25000 - 1
FUNCTIONVIRADDRcounter = 27000 - 1 # BLOCK of 3000 spaces
PARAMSINTcounter = 30000 - 1
PARAMSFLOATcounter = 33000 - 1
PARAMSCHARcounter = 36000 - 1 # BLOCK of 4000 spaces
POINTERScounter = 40000 - 1 # LAST BLOCK
```

We start with block of 2000 spaces, going through our possible type of variables we must store, function results that also need to be saved, and actual quadruple addresses in the pointers. Some blocks have more than 2000 spaces, such as the possible function values, or the storage space of char parameters.

We also handle a lot of data structures to help with the compilation process, which can be seen in the following image:

```
#####-----GLOBAL VARIABLES AND METHODS -----#####

#### PYTHON SETS, MUTABLE, ORDER OF ELEMENTS NOT IMPORTANT#####

temporalsCounter = 0
SPECIALMETHODScounter = -1
CURRENTcontext = 'g'
CURRENTtype = ''
CURRENTfuncname = ''
```

Each one was used in the compilation process, some more than others, and their descriptions is as follows:

- THETABLEoffunctions: The central set where all the functions are stored, with their ids, size, initial address, and variables. Due to not needing to heed a certain order, this is a set, which speeds up the search process.
- THEGLOBALVARset: Like the above set, but storing the information of globals, with their id, virtual address, and type and related information. Also, a set with the same benefits.
- THELOCALVARset: Same as THEGLOBALVARset, but with locals. Capable of being flushed to make space for new local variables.
- THEPARAMETERSset: Backup and debugging tool for parameter storage. Deprecated for stacks (using lists)
- THECONSTANTSset: Same as the the GLOBALVARset, but with constants.

- GLOBALNAMESlist: Structure to store the actual written names of the global variables, to prevent duplication. On second look, this should be a set, or be folded into THEGLOBALVARset.
- LOCALNAMESlist: Same use as the above structure, but with local variables. Also shares the same caveats as THEGLOBALNAMESlist and should be deprecated.
- QUADRUPLESlist: MOST important data structure, which stores the compiler output as a list of quadruple objects, which we have already described earlier. Due to the need to be outputted to a Virtual Machine, its vastly preferable that the structure maintains its order, so that the reading of its data can be done directly, instead of sorting it in the importation process.
- CONSTANTSlist: Deprecated list, no longer on project
- CONTPARAMETERSlist: A list used as as a stack, used in the verification process of the call of a function in the neuralgic points. Due to the need of being popped in the process, is a list.
- PARAMETERSTABLElist: A list storing every data type for a function call. Due to being used as a verifier of the CONTPARAMETERSlist, which follows an ordered nature, the PARAMETERSTABLElist must also be ordered, hence a list.
- PARAMETERQUEUElist: A list that stores the virtual address of the parameters, due to being mated to the CONTPARAMETERSlist in the process of generating PARAM quads, it must be ordered, so it must be a list.
- SPECIALMETHODlist: The datastructure that the compiler uses to store constant values for the special method calls, directly accessed by the VM. Due to the nature of certain statistical methods, it must preserve its order, so it's a list.
- SPECIALMETHODaux: A nested structure of the special methods parameters, storing constants. Could be refactored.
- STACKOFoperands: It's the central stack to get the necessary quadruple structure of operands, works via virtual addresses so its values can be stored in the outputted quadruples. As seen in class, a stack.
- STACKOfoperators: The central stack for operator symbols, its destination its to be hashed via the HASHOFOPERATORSINquads, so that the output can be put directly into the quadruples. AS seen in class, a stack.
- STACKOftypes: The mirror stack of operators, but handling types, is used by global methods and the semantic cube so that the resultant quadruples are working as intended. Due to being a mirror of a stack, it also is a stack.
- STACKOFpendingjumps: A stack that stores the quadruple counters of the Quadruplelist, and is used to handle jumps. Due to the need of it to be to be a stack due to nesting for appropriate jump calls, is a list.
- STACKOfdims: Leftover of possible arrays of more than one dimension, currently used a backup storage of the operand in a vector.
- The rest are simple counters, simple sensors, placeholder values in the for iterators, and simple containers for storing function names and types.

Virtual Machine Description

Physical Computer Equipment, Language and Special Required Utilities

The same characteristics as used in the compiler description.

Memory administration during code execution

As described in class, compilers output intermediate machine code, and if available with an interpreter, this machine code can be managed to output actual operations. Due to this, most interpreters must be able to read the quadruples (if working with actual quadruples) and its elements and be able to output the specific operations associated with those quadruples. This can be done with certain generic elements, which can be seen here declared in our Virtual machine here:

```

48 ##### STACK OF MEMORY HANDLERS, GLOBAL VARIABLES, MEMORY CLASS AND MISC #####
49 STACKofexecs = []
50 PROCList = []
51 PROCCOUNTER = 0
52 globalsensor = True
53
54 class Memory:
55     def __init__(self):
56         self.memor = {} ### A SET FOR OUR MEMORY####
57

```

```

##### MEMORY INITIALIZERS #####
GLOBALmemory = Memory()
actualmemory = None

```

This are all recognized parts of a VM machine, and follows much of the same logic, but due to the nature of our quadruples, and its hashed operators, and stored quadruple counters, much of the interpreting work can be sped up and be processed via simpler methods, which is centered on a while loop looking at each quadruple by quadruple.

- **STACKofexecs:** Used as a stack of executions, primarily focused with function quadruples, meaning ERA's and ENDPROC's. Works with verifying interactions between values in an out of functions and accessing local memory for the address values. Via working of nested functions, must be a stack, which permits us to let memory enter a pseudo-dormant state.
- **PROCList:** A stack that works with the function quadruples, works via implementing the of functions executions, and allows to store the jumps.
- **PROCounter:** Simple counter that works with the quadruple counters to run the intermediate machine code. Normally follows an iterative process.
- **Globalsensor:** Simple sensor if we are not working inside functions.
- **Memory class:** A simple object, that stores an attribute set, which speeds up massively code lookups, in which we load the actual data of our variables, dividing

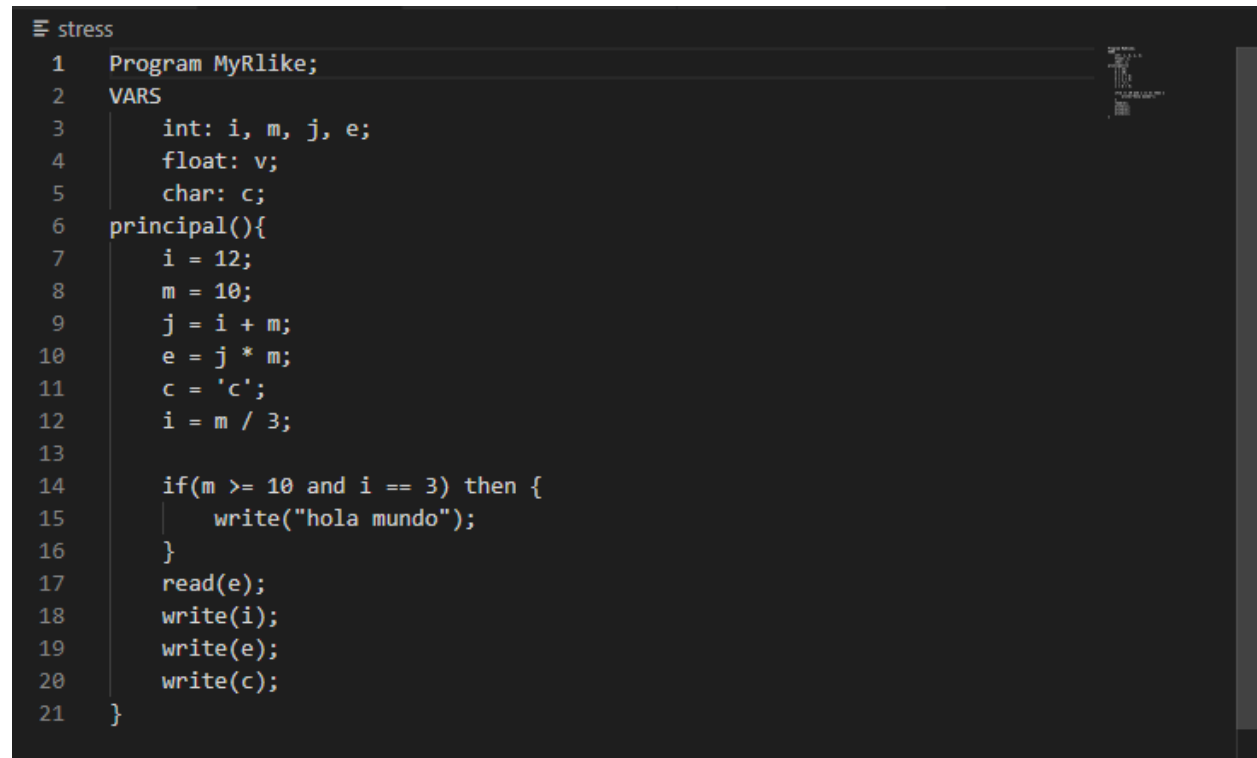

it in two objects, a GLOBALmemory object that is always active and available to be called, and an actualmemory, which is the local memory of the functions, capable of dormancy and only being flushed when entering an ENDPROC quadruple or a return quadruple.

With this data structures, and global methods and error handlings with some external handling of the constants table that was imported directly from the parser, we can have a simple Virtual Machine, which enters a while cycle, which reads directly the Quads object, which stored in the intermediate machine code, divides it into 5 variables, which are, index, operat, leftoperd, rightoperd, result, following the normal structure of a quadruple, and depending of the operat value which we know was hashed, we enter a list of elifs, and using the appropriate memory via the use of sensors and error checking, directly access the stored values of the virtual address, and via Python directly apply the operation. With a direct link between the virtual addresses used to output in the compiler, and the loading of a memory, that abstracts away the ability of a computer to read stored bytes as actual values, we get in the end a working compiler.

Working tests of the language

In here, we are going to show the three-step process of the original mir code, the intermediate machine code, and the execution process.

Stress testing.

```

1  Program MyRlike;
2  VARS

Reading

The image shows a Visual Studio Code editor window with the title bar 'reading - Compiladores2021 - Visual Studio Code'. The editor has a dark theme. The top menu bar includes 'Go', 'Run', 'Terminal', and 'Help'. Below the menu bar, there are two tabs: 'VM.py' and 'reading'. The 'reading' tab is active, showing a MYRLIKE program. The code is as follows:

```
1 Program reading;
2 VARS
3     float: a;
4     int: b;
5     char: c;
6 principal(){
7     write("Raading 3, a float, a int y a char");
8     read(a);
9     read(b);
10    read(c);
11    write("Results: ", a,b,c);
12 }
```

The image shows a Visual Studio Code window with a file named 'reading' open. The code is written in the Myrli language and defines variables of type float, int, and char, then reads their values and prints them. Below the code editor, the 'TERMINAL' panel shows the output of the program's execution, including the prompt message, the input values (3.4, 9, x), and the resulting output ('Results: 3.4 9 x').

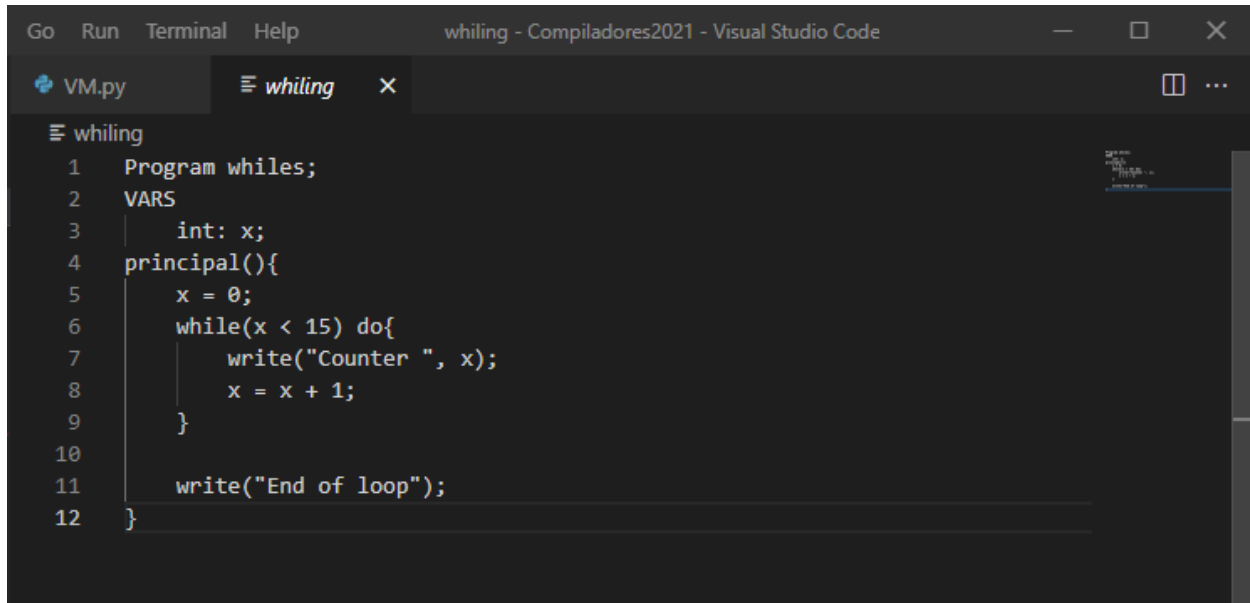

```
1 Program reading;
2 VARS
3     float: a;
4     int: b;
5     char: c;
6 principal()
7     write("Raading 3, a float, a int y a char");
8     read(a);
9     read(b);
10    read(c);
11    write("Results: ", a,b,c);
12
```

Recursion above and iteration below
6765
PS C:\Users\Usuario\Documents\GitHub\Compiladores2021>

The image shows a Visual Studio Code editor window with the file 'Quads.mir' open. The file contains a list of 42 lines of Myrli code, which are pairs of integers separated by a tilde (~). Line 40 includes a comment: "Recursion above and iteration below".

Below the editor, the 'TERMINAL' panel is active, showing the output of running a Python script 'VM.py'. The script processes the 'find' and 'fibonacci' files. For 'find', it outputs '3628800' and 'END LOOP'. For 'fibonacci', it outputs '6765' and 'Recursion above and iteration below'.

USER MANUAL

If you are looking to use this language as a learning tool or just to explore the efforts of a young IT engineer, you must follow the following steps:

1. Clone the project at the indicated repository:
<https://github.com/A00815749/Compiladores2021>
2. Have your environment ready, which includes the requirement of python 3. (This software was mainly developed on Python 3.9.0)
3. Install the libraries that were used in the technical manual, in the Special Utilities section.
4. Navigate to the folder with your programming environment of choice. Make sure you have all the required files
5. On terminal execute in python the VM.py file

```
2774.3838844323210
7697867.254545454
PS C:\Users\Usuario\Documents\GitHub\Compiladores2021> python VM.py
Nombre del archivo para compilar: stress
Llego al final de la gramatica, aceptado
```

6. When prompted with the following message, enter the name of the file you want to compile (make sure that the file is inside the same folder as the compiler)

```
7697867.254545454
PS C:\Users\Usuario\Documents\GitHub\Compiladores2021> python VM.py
Nombre del archivo para compilar: stress
Llego al final de la gramatica, aceptado

hola mundo
34
3
34
'c'
```

7. The file is going to be processed, and if working as intended, shall create the intermediate code machine, and display working results at terminal. If not, there are various error codes to see where the code went wrong if you are so interested.
8. Final note, you can directly see the source code of both the compiler and virtual machine, and if you are interested, at least 95% of the code is commented, so if you are curious, give it a read.

Video Demo file or link shall be directly appended to the project folder.
